Industry: ··· Niigata Seimitsu Co., Ltd., Yamamoto System Design, Inc., Hitachi Engineering Co., Ltd. (current: Hitachi Information & Control Solutions, Ltd.), and others
 Academia: ··· University of Tsukuba, and Tsukuba College of Technology (current: Tsukuba University of Technology)
 Government: ··· National Institute of Advanced Industrial Science and Technology (AIST)

Main Results of City Area Program

1. Application of Fluency Information Theory to Next-Generation Multimedia Products

Signal conversion technology based on Fluency Information Theory was developed and applied to the manufacturing of advanced multimedia products, including high-quality world-class audio equipment, a dialogic DTP system with high resolution and scalability, and image-processing LSI for high-resolution TV.

These achievements have won many awards, including the 4th Funai Information and Scientific Promotion Award, the 30th Inoue Harushige Award, the Nihon Printing Society Paper Award, and the Print Asahi Association Prize, providing opportunities to hold independent sessions at international academic societies such as AUTM.

Moreover, technology based on Fluency Information Theory is highly regarded as the international de facto standard technology for multimedia systems.

2. Development of a ubiquitous stereovision device (USVD)

We developed a USVD and submitted a patent application. The USVD enables the automatic and stable extraction of individual moving tracks from real-time scene images taken by stereo-cameras, and enables the automatic analysis of a large amount of time-series image data. The attainment of the desired properties of the prototype USVD were confirmed by practical feasibility studies conducted at various sites, including a train-station platform, a railway crossing, and a retail store.

The USVD technology was transferred to collaborating enterprises, and contributed to the establishment of a venture enterprise in December of 2004.

Approaches after Completion of Project

The project described above has been succeeded by a new project promoted by a collaboration between Tsukuba University, the National Institute of Advanced Industrial Science and Technology (AIST), and the National Agriculture and Food Research Organization (NARO). The new research theme is "Development of a Ubiquitous Visual Information Surveillance System for Safe and Secure City Life." This theme will conduct R&D into image-related IT with the aim of improving safety and security for city residents.

1. Progress in the adoption of Fluency Information Theory as the de facto standard for multimedia systems

In terms of the enhanced application of signal conversion technology based on Fluency Information Theory and its adoption as the de facto standard, practical LSIs for processing signal information for individual multimedia (e.g., audio, printing, video, TV) are being produced as part of an industry-academia-government cooperation. We also plan to establish a research-contract venture company based on this technology.

2. Development of intelligent surveillance systems based on a ubiquitous stereovision device (USVD) and other technology

Feasibility experiments regarding USVD were performed over a period of 6 months at the Aichi Expo site, confirming the effectiveness of USVD. Cooperative research has begun with several companies regarding the application of USVD technology to next-generation surveillance systems. In addition, efforts are underway to (1) develop a cubic higher-order auto-correlation (CHLAC) algorithm that enables the automatic detection of anomalous events, and (2) apply this algorithm to intelligent surveillance systems.

Image enlargement process
 Enabling high resolution enlargement of DTP image

Demonstration experiment

Date	Friday, March 25, 2005 - Thursday, September 22, 2005 (6 months)
Time	9:00am - 5:00pm (45 minutes from opening to closing)
Floor surface luminance	1 - 300lx (for the place in sunlight near the exit: 100lx)
Camera layout	Camera in each corner of 20 square area to reduce the number of people walking tool camera
Color image and disparity image	Color for 1 minute 30 seconds / 12 times per day / 6 months
Top of human heads tracking data	200k lines including image recording, around 370 million frames
Frame rate	Image recording: around 15 frames/sec. Top of human heads recorded data: around 12 frames/sec.
Color image	120 x 180 pixel
Reconfiguration in three dimension	Calculation with resolution 300 x 240

Demonstration experiment at EXPO 2005 Aichi

●Core Research Organizations

Osaka Prefecture University, Osaka University,
 Technology Research Institute of Osaka Prefecture

●Main Results of City Area Program

- 1. Establishment of fabrication technology for an anti-reflection structured surface**
 We established the technology to produce optical parts with low reflection using a super-precision mold. Optical parts with low reflection rates (as low as 1%) for the full range of visible light were successfully fabricated by molding optical resin using a die with a nano-structure surface. This made it possible to produce high-performance and low-cost optical components without the need for conventional dielectric multilayer coating. We expect to improve image quality by applying this technology to optical lenses for digital cameras and other devices.
- 2. Development of spectroscopic measurement technology for ultrafast phenomena (ultrafast optical spectrogram scope)**
 To measure the chemical reaction process in the femtosecond range, ultrahigh-speed optical communication signals, and the reactive process of fragile biomaterials such as cells and protein, we developed technology with the following characteristics: 1) high sensitivity (1 fJ or less), 2) single shot, and 3) simultaneous imaging in the time and wavelength domains. Using this technology, a photochemical reaction process involving a cyanic organic pigment was successfully measured in the sub-picosecond range. Application of this technology to microscopes and optical communications technology will advance research into biological and molecular chemistry and optical communications technologies.

Ultrafast optical spectrogram scope (prototype with microscope)

●Approaches after Completion of Project

- 1. Development and promotion of practical technology for fabricating an anti-reflection structured surface**
 A technology was established for fabricating a die by micro-machining the metal surface directly, which rendered electroforming technologies unnecessary. As a result, the curvature accuracy of the lens surface was improved, and the fabrication cost of the metal mold was reduced. New techniques for the fabrication of nanostructures on heat-and light-resistant glass are being investigated as part of the NEDO project (next-generation optical control material/element technology project), which began in FY2006. This technology will contribute to the production of optical glass parts used in high-quality digital cameras, LCD projectors, and blue laser optical components, etc. To popularize this technology, we currently provide product samples and training in the use of the technology to corporations.
- 2. Development of an ultrafast optical spectrogram scope**
 To apply this technology to devices for measuring various material properties, a joint project was established with a private company to select items suitable for commercialization among the technologies developed to date. A second collaboration with a private company is engaged in promoting the development and patenting of standard signals, and is applicable to a broad range of applications.

Kumamoto University

●Main Results of City Area Program

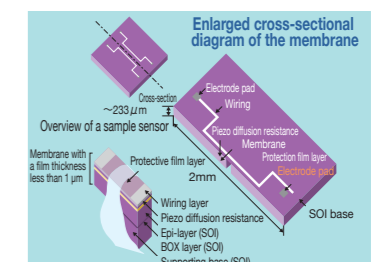

- 1. Development of a biocompatible microsensor (prototype) having various functions, including physiological data transmission/reception and biological/physiological measurement**
 Biological/physiological measurement is extremely important in animal experiments. In particular, an important future goal is measurement methods applicable to animals in an unrestrained state. The R&D undertaken as part of this project developed a membrane-type pressure sensor and electrode-type sensor for measurements of heart beat, among other uses. We succeeded in developing a biocompatible microsensor with an electrode-type heart-beat sensor. We also succeeded in developing a biocompatible coating agent for microsensors embedded in the living body of experimental animals.
- 2. Development of a network-type MEMS workshop**
 With the cooperation of institutions and enterprises in the Kumamoto area involved in the development of a small-sized membrane-type pressure sensor, we held a "MEMS Workshop" with the network of small-lot/ more much variety was completed. In this regard, sensor devices, including ultra-small pressure sensors that require microprocessing, are currently ready for production.

Smart microchip

Biocompatible coating materials

Pressure sensor

●Approaches after Completion of Project

- 1. Development of a living-body adaptive-type microsensor (smart microchip) equipped with living body information analysis, sending/receiving, and identification functions**
 Ongoing research aims to advance the findings of the Development Stage (2005) from experiments involving non-human animals to those involving humans, using smart microchips with an integrated circuit, antennae, extracting/processing systems for physiology data, instrumental systems for a hypodermically embedded sensor system, materials for pasting and parts for bio elements and ultra small and highly sensitive sensors. By combining these technologies, we aim to develop a "Next-generation Biological Information-Processing Chip for Human Movement and Physiological Data."
- 2. Promotion of different research fields, especially the integration of engineering and medical sciences**
 The "Research for Intelligent System Technology in Kumamoto" (RIST) project, which has the aim of solving problems in the field of medical services, was established following the "Medical and Engineering Collaboration Study Conference" to inspire new technologies with the potential to be developed by member enterprises and researchers. Therefore, RIST plays an essential role in building a firm foundation for ongoing academia-industry-government collaborations in various research areas.
- 3. Development of a Three-dimensional Lithography Method**
 We sought to develop a "Three-dimensional Lithography Method" as a new technological component of the "City Area Program at the Development Stage," and ultimately produced a new microcoil. This technology represents an advancement in the maskless-lithography method currently being developed as part of the project titled "Collaboration of Regional Entities for the Advancement of Technological Excellence" that preceded the "City Area Program." This is expected to be an important future technology in the field of semiconductor research.
